# **COLLECTION OF EVIDENCE FROM HEAVY COMMERCIAL VEHICLE INCIDENTS**

**By: Cst. Glenn Miller  
Surrey RCMP**

**TECHNICAL MEMORANDUM**

**Submitted by  
Surrey RCMP**

**December, 1995**

**NOTE: Further information  
about this report can be  
obtained by calling the  
CPRC information number  
(613) 998-6343**

---

## **EXECUTIVE SUMMARY**

The incidence of heavy commercial vehicle collisions has risen dramatically. As a result the police traffic investigator is looking to new technology to collect the necessary investigation data. This memorandum compares five instruments - Shot Marker from Max Automotive, MEA Fifth Wheel Assembly, Bowmonk Skidman, the G-Analyst and the Vericom VC 200.

## **SOMMAIRE**

Le nombre de collisions impliquant des véhicules lourds commerciaux a augmenté de façon considérable. Les policiers doivent donc se tourner vers de nouvelles technologies pour recueillir les données nécessaires à leurs enquêtes. Cette étude comparative porte sur cinq appareils : le Shot Marker de Max Automotive, le Fifth Wheel Assembly de MEA, le Skidman de Bowmonk, le G-Analyst et le Vericom VC 200.

# Overview

## Commercial Vehicle Collisions - The Current Situation

The incidence of heavy commercial vehicle collisions is rising dramatically. Claims for Commercial Vehicle Collisions increased by more than \$18 million between 1992 and 1994.

For the amount of distance travelled, heavy commercial vehicles are involved in relatively few collisions. The collisions they do become involved in, however, tend to be very serious. The problem with the lack of frequency means that there is little opportunity to get proficient at collecting the required data from these incidents.

With this in mind, we set out to do some testing to validate some new instrumentation which is becoming commonplace in commercial vehicles, and some new devices which could be used after the fact by Collision Analysts / Reconstructionists.

This seminar was designed to give you adequate knowledge of the available instrumentation, and to provide data which can be used to validate the findings of onboard instrumentation. There is an identifiable need to continue this research, and it is hoped that this information will give you a basis to begin.

Testing took place on two days, the 20th and 21st of November 1995, at Boundary Bay. Two large commercial vehicles were instrumented and tested. One was a 1995 Peterbilt tractor from J&R Rentals, and the other was a Kenworth tractor from Canada Safeway. The Peterbilt was equipped with self adjusting brakes and was pulling a trailer which was also rented for the testing. The Canada Safeway tractor was equipped with the Cummins Engine Management system which records data relevant to fleet management. This system also records panic stops.

# *Instruments Tested*

## Shot Marker from Blue Max Automotive

Both vehicles were equipped with a shot marker which was attached to the rear cross member of the tractor. This device was wired to the brake light on the tractor.

This shot marker uses a door lock motor (as opposed to a solenoid) and had been tested previously and found to operate with a comparable response time to solenoid equipped bumper gun systems.

This particular design was patterned after a previous model, which had been found to be extremely reliable.

## MEA Fifth Wheel Assembly and Computer

MacInnis Engineering Associates donated the use of their Fifth Wheel and computer for acquiring speed and deceleration data from the tests. They also donated their time and experience to interpreting the results.

The fifth wheel assembly was attached to the rear cross member of the tractor and was calibrated at the scene. The data was sampled 32 times per second from approximately one second prior to braking to 15 seconds after the onset of braking.

The data collected was then saved in a spreadsheet application for interpretation.

# **Data Collection for Heavy Commercial Vehicle Collision Investigation**

## **A Preliminary Investigation**

---

### **BOWMONK SkidMan *g-force Instrument***

Two Bowmonk SkidMan analyzers were used. One was certified accurate from the factor) and the second was displaying the caption, "I Seed Calibration!". The Bowmonk SkidMan demands calibration after a set time limit and this message doesn't necessarily indicate a fault in the system,

The two Bowmonk devices reliably registered similar readings.

The Bowmonk SkidMan is a self contained unit in a hard case which can easily be set up and armed. It could have some practical applications in the realm of enforcement as well.

### **G-Analyst *g-force Instrument***

A G-Analyst was also used in the tests on day 2. It consists of two parts, the computer and display unit which contains the data collected, and the sensor unit which is mounted securely on the floor.

Caution should be exercised when using instruments such as the Vericom VC200 and the G-Analyst to determine road friction coefficients at collision sites.

The Vericom results should incorporate the road grade in the direction of the skid because the instrument, when used correctly, is calibrated at the actual test site.

The G-Analyst works differently. Its calibration sequence is designed to determine a true level. Its acceleration results must therefore be compensated for grade.

### **VERICOM VC 200**

The VERICOM was loaned to the testers by the Delta Municipal Police Department. It is designed to measure g-force and to calculate the mu, by tripping automatically at the onset of braking. At times it failed to trip and therefore there was no data collected from this instrument. The VERICOM failed more often than any of the other devices, but this could have been due to a lack of experience with the product.

Caution should be exercised when using instruments such as the Vericom VC200 and the G-Analyst to determine road friction coefficients at collision sites.

The Vericom results should incorporate the road grade in the direction of the skid because the instrument, when used correctly, is calibrated at the actual test site.

***Data Collection for Heavy Commercial Vehicle Collision Investigation***  
*A Preliminary Investigation*

---

The G-Analyst works differently. Its calibration sequence is designed to determine a true level. Its acceleration results must therefore be compensated for grade.

# Testing *Methodologies*

## Purpose of the Testing

The purpose of the testing was to determine whether the instruments tested gave similar results. This was an essential component of the evaluation process. The most glitzy piece of equipment is of absolutely no value if it doesn't produce accurate, consistent data with a high degree of reliability.

To this end, the trucks were equipped with a fifth wheel recording device which was connected to a computer for the purposes of downloading the wheel travel. The fifth wheel was attached to the rear cross member of the tractor unit. The computer was programmed to collect wheel speed data at a rate of 32 samples per second. The fifth wheel assembly was provided by MacInnis Engineering Associates and was installed and calibrated by engineers from MacInnis. It was operated from the computer in the cab of the truck, and was run by an engineer from MacInnis.

The G-Analyst was provided for the second day of testing by Constable Lorne Derkson of the Langley RCMP. It was installed and operated under his supervision. It was configured to collect the data throughout the day and the data was downloaded following all of the tests.

A shot marker was also installed on the truck and was mounted on the rear cross member of the tractor immediately next to the fifth wheel assembly. The shot marker was connected to the brake lamp assembly at the rear of the tractor.

The Vericom VC200 was provided by the Delta Municipal Police Department and was mounted according to the manufacturer's directions on the front windscreen of the truck. It was set to automatically trip and record each stop, but it experienced some failures. The results charts simply show a zero where the Vericom VC200 failed to trip.

The truck from Safeway Canada was equipped with an engine management system called the Road Relay TM. It is an advanced system which records various operating parameters. Of interest to Collision Investigators is it's ability to record panic stops. The Road Relay TM detects

## **Data Collection for Heavy Commercial Vehicle Collision Investigation**

### ***A Preliminary Investigation***

---

a panic stop and keeps the data from the 45 seconds immediately preceding the panic stop, to a point 14 seconds following the onset of braking. The parameters kept are; speed, RPM, Clutch use and Brake use. These parameters can be printed out for a second by second analysis.

The Bowmonk SkidMan data was printed out and then downloaded after the testing for analysis. The results are presented in table format in the section titled *Findings*.

Process for determining the g results of each instrument

#### ***Bowmonk SkidMan***

The g values of the results from the Bowmonk Skid-Man devices is calculated by the instrument by default. The Mean Deceleration figure was used for the purposes of comparison, as it is the most straightforward method of collecting the data.

#### ***Shot Marker (Bumper Gun)***

The normal process for calculating mu was used with the shot marker. The speed was measured by Radar, the distance from the chalk mark to a point beneath the final rest position of the shot marker was measured, and the results were applied to the formula to determine mu from Speed and Distance.

$$\mu = \frac{S^2}{254D} \quad \text{or, in this case} \quad g = \frac{S^2}{254D}$$

#### ***MEA Fifth Wheel***

The fifth wheel presented a small problem, but a workaround was found. On the day of testing, there was no operable device to provide a signal to the computer the instant the brake pedal was depressed. This meant, that there was no corresponding data stored as to when the brakes were actually applied. Since this is an air brake equipped vehicle, the system lag would not be calculated and therefore, the samples obtained could differ from some of the other instrumentation.

The workaround was relatively simple. Since the fifth wheel samples distance 32 times per second, and calculates the deceleration force with each sample, the standard method of calculating the Mean Deceleration is to average all of the readings taken during braking. The distance the vehicle travelled from the onset of braking to final rest was known from the results of the shot marker test.

Therefore, the distance from the shot marker test was subtracted from the final rest distance of the fifth wheel, and the point where the brakes were applied could be easily located within the data.

### *Vericom VC200*

The Vericom VC200 was set to automatically trip when it sensed deceleration. It then calculated the results automatically and displayed them on a screen. The Vericom VC200 displays two results, both a peak reading and an Average g value. The Average g was used for our purposes.

Caution should be exercised when using instruments such as the Vericom VC200 and the G-Analyst to determine road friction coefficients at collision sites.

The Vericom results should incorporate the road grade in the direction of the skid because the instrument, when used correctly, is calibrated at the actual test site.

### **G-Analyst**

The G-Analyst was also set to trip automatically when it sensed a sudden deceleration. It was set to collect the data from the tests and was removed from the vehicle. The data was then downloaded to a floppy disk for analysis later.

The G-Analyst data analysis program is an artifact of the days of DOS software. Had the limitations of this software been known prior to downloading the data, it would have been saved in a .pm format to permit analysis via a spreadsheet application. The g force was calculated and registered by the G-Analyst at a rate of ten samples per second. The results of these scans were averaged over the total stopping distance to calculate the average g force. The results of these calculations are shown in the table in Appendix "A".

Caution should be exercised when using instruments such as the Vericom VC200 and the G-Analyst to determine road friction coefficients at collision sites.

The G-Analyst calibration sequence is designed to determine a true level. Its acceleration results must therefore be compensated for grade.

# Findings

## Similarities

The results, taken in their totality, show a remarkable consistency, given the wide range of technologies which calculated the data.

For the purposes of charting the data collected, when an instrument failed, the data is represented as zero. This ensures that there will be no misleading information in the charts.

To fully understand the charts, the details of the tests have been assembled into Table form.

Test Notes		
Test	Vehicle	Notes
1	1995 Peterbilt with trailer	Lock-up attempted at ~50 km/h. Data failure with fifth wheel. Concrete surface, dry. Radar @ 48 km/h.
2	1995 Peterbilt with trailer	Lock-up attempted at ~50 km/h. Concrete surface, dry. Radar @ 49 km/h.
3	1995 Peterbilt with trailer	Lock-up attempted at ~50 km/h. Concrete surface, dry. Radar @ 48 km/h.
4	1995 Peterbilt with trailer	Lock-up attempted at ~50 km/h. Concrete surface, dry. Radar @ 49 km/h. Both SkidMan units placed side-by-side in cab of truck.
5	1995 Peterbilt with trailer	Lock-up attempted at -50 km/h. Concrete surface, dry. Radar @ 50 km/h. SkidMan 2 placed on rear of trailer. 16.60 meters rearward of SkidMan 1.
6	1995 Peterbilt with trailer	Lock-up attempted at -90 km/h. Concrete surface, dry. Radar @ 85 km/h. SkidMan 2 placed on rear of trailer. 16.60 meters rearward of SkidMan 1.

**Data Collection for Heavy Commercial Vehicle Collision Investigation**  
*A Preliminary Investigation*

7	1995 Peterbih with trailer	Lock-up attempted at -80 km/h. Concrete surface, dry. Radar @ 84 km/h. Computer for fifth wheel failed. SkidMan 2 was placed on roof of tractor.
8	1995 Peterbilt with trailer	Lock-up attempted at -80 km/h. Concrete surface, dry. Radar @ 81 km/h. SkidMan 2 was placed on roof of tractor.
9	1995 Peterbilt with trailer	Lock-up attempted at ~100 km/h. Concrete surface, dry. Radar @ 98 km/h. SkidMan 1 was tilted at -7% to the front, SkidMan 2 was tilted -140 from the front.
10	1995 Peterbilt with trailer	Lock-up attempted at ~100 km/h. Concrete surface, dry. Radar @ 106 km/h. SkidMan 1 was triggered by the pedal force transducer, SkidMan 2 was internally triggered.
11	1995 Peterbilt with trailer	Lock-up attempted at -50 km/h. Concrete surface, dry. Radar @ 49 km/h.
12	1995 Peterbilt with trailer	Lock-up attempted at -50 km/h. Asphalt surface, dry. Radar @ 60 km/h. Brakes were backed off manually to the legal limit (2 inches)
13	1995 Peterbilt with trailer	Lock-up attempted at -50 km/h. Asphalt surface, dry. Radar @ 57 km/h. Brakes were backed off manually to the legal limit (2 inches)
14	1995 Peterbilt with trailer	Lock-up attempted at -60 km/h. Asphalt surface, dry. Radar @ 56 km/h. Brakes were backed off manually to the legal limit (2 inches) NO STEERING AXLE BRAKES.
15	1995 Peterbilt with trailer	Lock-up attempted at -60 km/h. Asphalt surface, dry. No Radar reading as Shot Marker failed. Brakes were backed off manually to the legal limit (2 inches) NO STEERING AXLE BRAKES.
16	Canada Safeway Kenworth	No Trailer. Tests to validate the Road Relay system. Panic stop from 60 km/h. No radar reading as the Shot Marker failed. Results from Road Relay matched those from fifth wheel.
17	Canada Safeway Kenworth	No Trailer. Tests to validate the Road Relay system. Panic stop from 60 km/h. No radar reading as the Shot Marker failed. Results from Road Relay matched those from fifth wheel.
18	Canada Safeway Kenworth	No Trailer. Panic stop from 32 km/h. No radar reading as the Shot Marker failed.
19	1995 Peterbilt with trailer	Lock-up attempted at -60 km/h. Asphalt surface, wet. Radar @ 58 km/h. Brakes were backed off manually to the legal limit (2 inches) Brakes were run until HOT.

**Data Collection for Heavy Commercial Vehicle Collision Investigation**  
*A Preliminary Investigation*

20	1995 Peterbilt no trailer	Lock-up attempted at -50 km/h. Asphalt surface. wet Radar @ 50 km/h. Brakes were backed off manually to the legal limit (2 inches) Brakes were run until HOT.
21	1995 Peterbilt no trailer	Lock-up attempted at -50 km/h. Asphalt surface, wet. Radar @ 48 km/h. Brakes were backed off manually to the legal limit (2 inches) Front brakes were completely backed off. Brakes were run until HOT.
22	Plymouth Voyager	Bumper Gun Failed
23	Plymouth Voyager	Skid-Man 1 was mounted on the floor between the front seats. Skidman 2 was placed in a cupboard at the rear of the vehicle, 1.45 meters to the rear and 0.72 meters higher. Speed from Radar was 55 km/h and the slide distance was 19.00 meters.
24	Plymouth Voyager	SkidMan 1 was mounted on the floor between the front seats. SkidMan 2 was placed in a cupboard at the rear of the vehicle, 1.45 meters to the rear and 0.72 meters higher. Speed from Radar was 64 km/h and the slide distance was 25.75 meters.
25	Plymouth Voyager	SkidMan 1 was mounted on the floor between the front seats. SkidMan 2 was placed on the floor at the rear of the vehicle, 1.45 meters to the rear. Speed from Radar was 61 km/h and the slide distance was 23.90 meters.
26	Plymouth Voyager	SkidMan 1 was mounted on the floor between the front seats. SkidMan 2 was placed on the floor at the rear of the vehicle, 1.45 meters to the rear. Speed from Radar was 62 km/h and the slide distance was 23.90 meters.
27	Plymouth Voyager	Both SkidMan devices mounted on floor side by side. Speed from Radar was 62 km/h and the slide distance was 24.65 meters.
28	Plymouth Voyager	Both SkidMan devices mounted on floor side by side. Speed from Radar was 62 km/h and the slide distance was 24.65 meters.

The information in the table above, should be used when reading the following table and chart. Most often, discrepancies between instrumentation can be explained from the information in the table.

**Data Collection for Heavy Commercial Vehicle Collision Investigation**

28	0.000	0.000	0.000	0.654	0.674	0.600

NOTE: Where the chart shows a result of "0.000", this means that the system either failed to provide a reading, or was not used for that test.

## Comparison of Results Grouped by Test

## Comparison of Results

### Instruments Compared by Test

## **Plymouth Voyager Tests**

### **Results Grouped by Test**

This chart shows the representative value of each instrument at each test. As it ignores zero values, which indicate that an instrument failed, it shows the relationship between each instrument. If all of the instruments returned an identical value, they would all share equal space on the pie chart.

The purpose of the tests with the Plymouth Voyager was to attempt to confuse the Bowmonk SkidMan instruments. As the chart indicates, all attempts to confuse this instrument failed.

The chart on the next page is identical in nature, but only shows the tests involving the truck from Canada Safeway. Since there were various equipment failures when testing the Canada Safeway truck, the data appears incomplete, however, it acts as an accurate representation of the relationships between the instruments which did function.

## Canada Safeway Truck Test Results

■ G-Analyst ■ Fifth Wheel ■ SkidMan 1

Of special interest here is the result from the G-Analyst in Test #18. More research will be necessary to understand this failure.

# *Appendix B*

## **Road Relay Tests**

The truck from Canada Safeway was instrumented with a fifth wheel to determine the accuracy of the Road Relay system.

The Road Relay results of the first panic stop showed a speed of 39 miles per hour immediately preceding braking action. The figure for the second panic stop was 37 miles per hour. It was not possible to match the results during braking, only the figure immediately preceding braking action was accurate. This is likely due either to the fact that the truck's wheels are experiencing braking where the fifth wheel is free wheeling, or that the speed change is too rapid for the sampling system of the Road Relay.

The next two pages show the results from the fifth wheel as they pertain to the panic stop tests. The speeds match exactly to the speed obtained from the Road Relay.

The results for the first test of the Road Relay. The full second prior to braking is shown, as well as the braking point. The Speed registered prior to braking by the Road Relay was 39 mph.

**Data Collection for Heavy Commercial Vehicle Collision Investigation**  
*A Preliminary investigation*

File Name : TR_BR17.CSV									
Description : Truck braking tests									
Test Time and Date : 12:30:12 11/21/95									
Sampling Sequence : Completed Normally									
Sampling Rate : 32.00 Hz									
Sample Time before Trigger : 1.0 seconds ;									
Sample time after Trigger : 12.0 seconds ;									
Encoder Ports Sampled:									
Port A MEA 5th Wheel - Diameter : -0.658 meters (20000 PPR)									
Acceleration : Average Across 16 Time Slices
